

Are phase change materials suitable for thermal energy storage?

Phase change materials (PCMs) having a large latent heat during solid-liquid phase transition are promising for thermal energy storage applications. However, the relatively low thermal conductivity of the majority of promising PCMs ($< 10 \text{ W/(m} \cdot \text{K)}$) limits the power density and overall storage efficiency.

Do phase change materials reduce energy consumption?

Phase change materials (PCMs) possess exceptional thermal storage properties, which ultimately reduce energy consumption by converting energy through their inherent phase change process.

Can phase change materials mitigate intermittency issues of wind and solar energy?

Article link copied! Thermal energy storage technologies utilizing phase change materials (PCMs) that melt in the intermediate temperature range, between 100 and 220 $^{\circ}\text{C}$, have the potential to mitigate the intermittency issues of wind and solar energy.

What are the non-equilibrium properties of phase change materials?

Among the various non-equilibrium properties relevant to phase change materials, thermal conductivity and supercooling are the most important. Thermal conductivity determines the thermal energy charge/discharge rate or the power output, in addition to the storage system architecture and boundary conditions.

How much research has been done on phase change materials?

A thorough literature survey on the phase change materials for TES using Web of Science led to more than 4300 research publications on the fundamental science/chemistry of the materials, components, systems, applications, developments and so on, during the past 25 years.

What are the selection criteria for thermal energy storage applications?

In particular, the melting point, thermal energy storage density and thermal conductivity of the organic, inorganic and eutectic phase change materials are the major selection criteria for various thermal energy storage applications with a wider operating temperature range.

Compared with non-phase change thermal energy storage in A-CAES, high heat storage density and temperature stability of phase change materials (PCMs) make it superior to the former [17], [18], [19]. When PCMs go through a change in physical state, a large amount of latent heat is stored or released and there is no change of temperature.
